

Software Architecture Styles

CQRS Architecture

separates read and write operations for a data store. It enables independent scaling of read and write workloads and optimizes them separately.

Layered (n-tier) Architecture

separates software into logical layers

Orchestration Architecture

a central coordinator (often called an orchestrator) that directs the interaction between services. The orchestrator is responsible for managing the control flow and data flow between services.

MVP Architecture

derivative of the Model-View-Controller (MVC) pattern, which aims to separate the concerns of data management, user interface, and control flow.

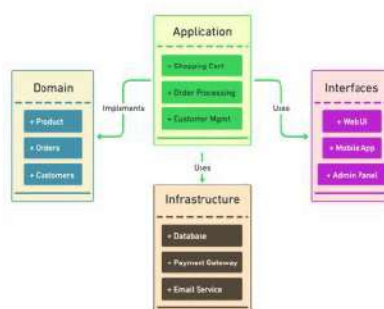

Event-Driven Architecture

promotes the production, detection, consumption of, and reaction to events.

DDD Architecture

focuses on the domain logic and complexity rather than the technology used.

Microkernel Architecture

separates a minimal functional core from extended functionality and customer-specific parts.

Microservice Architecture

This architecture designs a software application as a suite of independently deployable, small, modular services.

Space-Based Architecture

This resolves the issues of data consistency, reliable performance, and scalability for large-scale distributed systems.
